

What models track: Node Importance

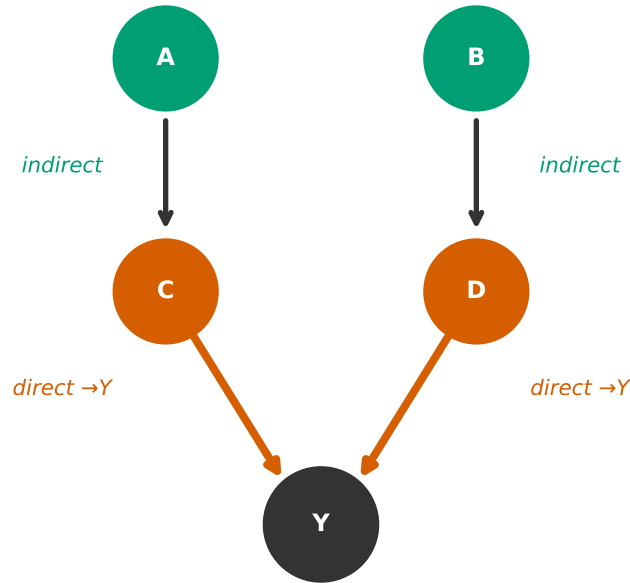

$$\beta = 0.014^{***}$$

Probe A (high betweenness) $\rightarrow$ large Δ
Probe B (low betweenness) $\rightarrow$ small Δ

What models also track: Outcome Proximity

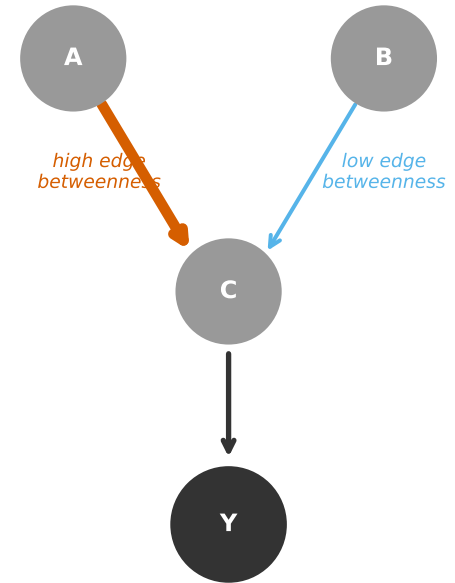

$$\beta = 0.012^{***}$$

Probe C,D (direct) $\rightarrow$ +1.2pp larger Δ
than A,B (indirect), same betweenness

What models ignore: Edge Topology

$$\beta = 0.001, \text{ n.s.}$$

Edge betweenness does NOT
predict shift magnitude
